

*Day 3

- * **Method** – Methods facilitate communication between objects.
 - * **Functions** – Functions represent actions an object can take. They are also at times referred to as methods.
- * **Object** – An object is a real-time representation of any entity
- * **Encapsulation** - The process of wrapping property and function within a single unit is known as encapsulation.
- * **Inheritance** - It is a concept in which some property and methods of an Object is being used by another Object
- * **Class** – A class in terms of OOP is a blueprint for creating objects. A class encapsulates data for the object.
 - * **Constructors** – Responsible for allocating memory for the objects of the class.

* Object-Oriented Programming Concepts

- * Object Orientation, considers a program as a **collection of objects** that communicates with each other via mechanism called **methods**.
- * A class definition can include the following –
 - * **Constructors** – Responsible for allocating memory for the objects of the class.
 - * **Functions** – Functions represent actions an object can take. They are also at times referred to as methods.

* Classes

*Creating Objects

- *To create an instance of the class, use the **new** keyword followed by the class name.

*Accessing Functions

- *A class's attributes and functions can be accessed through the object. Use the **'.'** **dot notation** (called as the period) to access the data members of a class.

*Accessing Functions

- * JavaScript supports class syntax since ES6, but only now were private fields introduced. To define a private property, it has to be prefixed with the hash symbol: #.

```
class Flower {  
  #leaf_color = "green";  
  constructor(name) {  
    this.name = name;  
  }  
  get_color() {  
    return this.#leaf_color;  
  }  
}  
  
const orchid = new Flower("orchid");  
console.log(orchid.get_color()); // green  
console.log(orchid.#leaf_color) // Private name #leaf_color is not defined
```

*Class Private Fields

- * a class method can now be declared with the static keyword and called from outside of a class.

```
class Flower {  
  constructor(type) {  
    this.type = type;  
  }  
  static create_flower(type) {  
    return new Flower(type);  
  }  
}  
const rose = Flower.create_flower("rose"); // Works fine  
console.log(rose);
```

*Static Fields

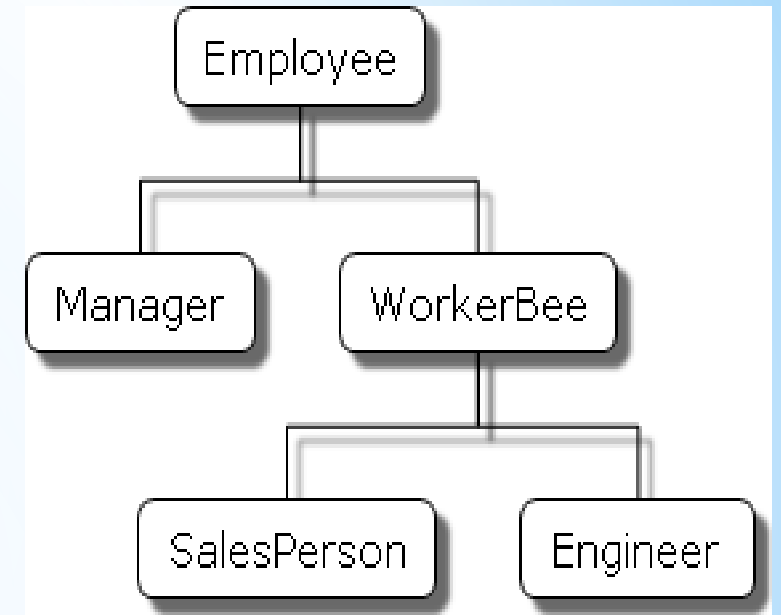

- * Inheritance is the ability of a program to create new entities from an existing entity - here a class. The class that is extended to create newer classes is called the **parent class/super class**. The newly created classes are called the **child/sub classes**.
- * A class inherits from another class using the '**extends**' keyword. Child classes inherit all properties and methods except constructors from the parent class.

* Class Inheritance

- * **Method Overriding** is a mechanism by which the child class redefines the superclass method.
- * a child class to invoke its parent class data member. This is achieved by using the **super** keyword. The super keyword is used to refer to the immediate parent of a class.

* Class Inheritance and Method Overriding

- ❖ **Employee** has the properties **name** (whose value defaults to the empty string) and **dept** (whose value defaults to "**general**").
- ❖ **Manager** is based on **Employee**. It adds the **reports** property (whose value defaults to an empty array, intended to have an array of Employee objects as its value).
- ❖ **WorkerBee** is also based on **Employee**. It adds the **projects** property (whose value defaults to an empty array, intended to have an array of strings as its value).
- ❖ **SalesPerson** is based on **WorkerBee**. It adds the **quota** property (whose value defaults to 100). It also **overrides the dept** property with the value "**sales**", indicating that all salespersons are in the same department.
- ❖ **Engineer** is based on **WorkerBee**. It adds the **machine** property (whose value defaults to the empty string) and also **overrides the dept** property with the value "**engineering**".

***The employee example**

*The **XMLHttpRequest** object can be used to exchange data with a web server behind the scenes. This means that it is possible to update parts of a web page, without reloading the whole page.

*AJAX

- * **onreadystatechange** Defines a function to be called when the readyState property changes
- * **readyState**
 - * 0: request not initialized
 - * 1: server connection established
 - * 2: request received
 - * 3: processing request
 - * 4: request finished and response is ready
- * **responseText** Returns the response data as a string
- * **responseXML** Returns the response data as XML data
- * **status**
 - * 200: "OK"
 - * 403: "Forbidden"
 - * 404: "Not Found"
- * **statusText** Returns the status-text (e.g. "OK" or "Not Found")

*XMLHttpRequest Object Properties

2. Callbacks

1. callback:

- it is a piece of code(function) that can be passed to a function that performs an asynchronous action. (timers, I/O, http request ...etc.)
- after the async action runs and returns its result, the function can then call the passed function with the returned result.

```
function asyncAdd(a, b, callback) {  
  setTimeout(() => {  
    const c = a + b;  
    callback(c);  
  }, 2000);  
}  
  
asyncAdd(4, 5, (c) => {  
  console.log(c);  
});
```

You, a few seconds ago

Callbacks

2. callbacks had given us the capability to run asynchronous code.
3. But when things gets more complex, we usually end up with what is called “callback hell”
4. callback hell: it refers to nesting callbacks inside of each other ending up with the Pyramid of Doom
5. nesting callbacks reduce code readability and scalability.

```
asyncAdd(4, 5, (c) => {  
  asyncAdd(c, 8, (d) => {  
    asyncAdd(d, 10, (e) => {  
      asyncAdd(e, 15, (f) => {  
        asyncAdd(e, 15, (g) => {  
          console.log(g);  
        });  
      });  
    });  
  });  
});
```

2.1 CallBack Hell

```
01.  
02. pan.pourWater(function() {  
03.   range.bringToBoil(function() {  
04.     range.lowerHeat(function() {  
05.       pan.addRice(function() {  
06.         setTimeout(function() {  
07.           range.turnOff();  
08.           serve();  
09.         }, 15 * 60 * 1000);  
10.       });  
11.     });  
12.   });  
13. });  
14.  
15.  
16.  
17.  
18.  
19.
```

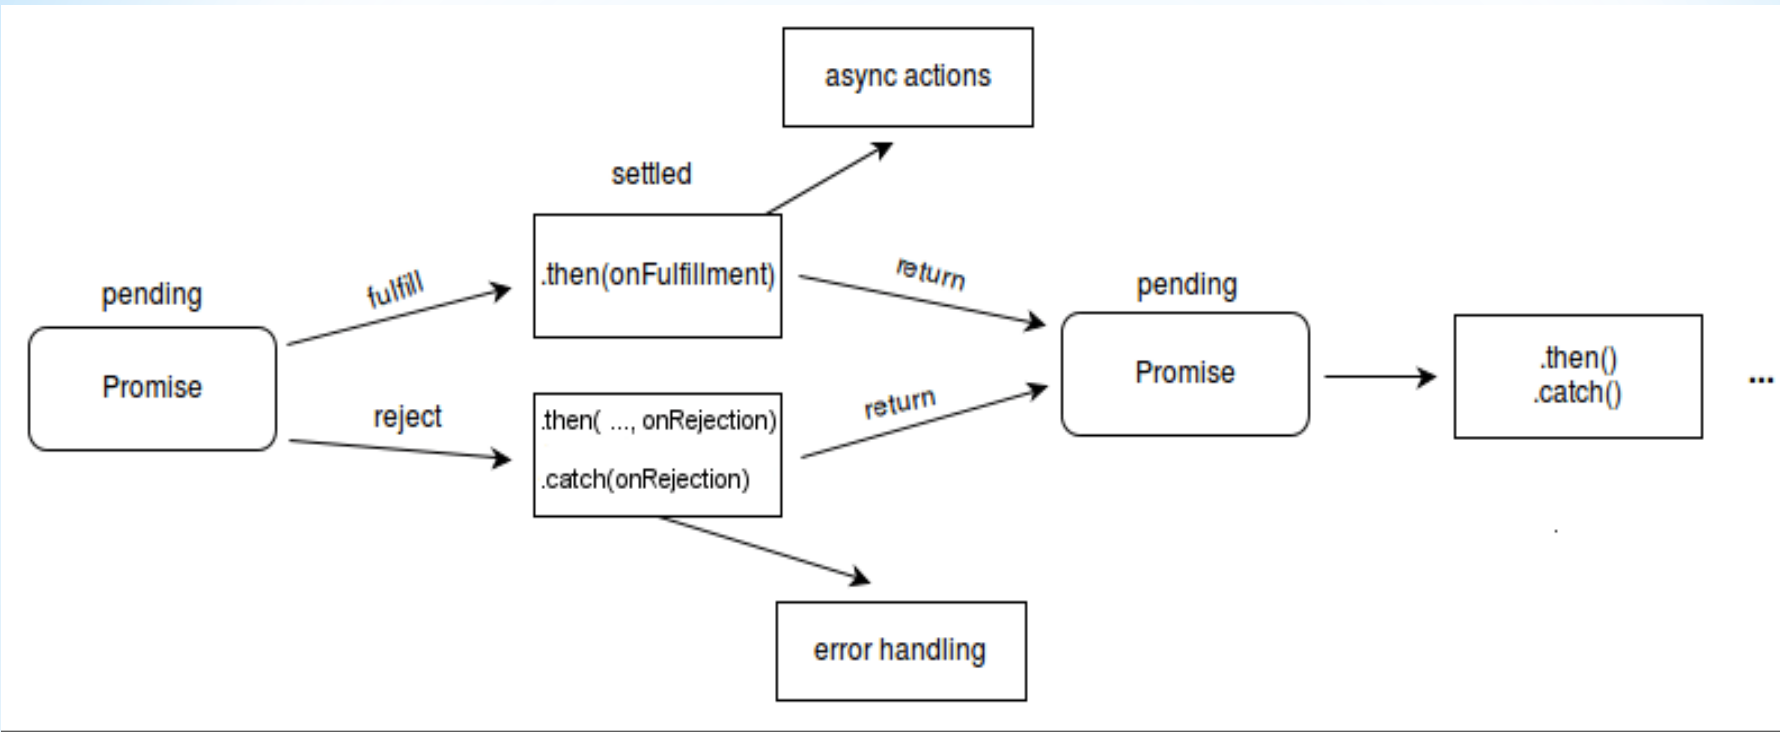

pyramid of doom

- * Promise for a value to be returned in a future
- * Can have three mutually exclusive states
 - * fulfilled
 - * rejected
 - * pending
- * Can be referred as deferred or future
- * Powerful for **asynchronous** / concurrent applications

* Promise

*Promise

```
let myPromise = new Promise(function (myResolve, myReject) {  
  // "Producing Code" (May take some time)  
  
  myResolve(); // when successful  
  myReject(); // when error  
});  
// "Consuming Code" (Must wait for a fulfilled Promise)  
myPromise.then(  
  function (value) {  
    /* code if successful */  
  },  
  function (error) {  
    /* code if some error */  
  }  
);
```

*Promise

```
function getData() {
  return new Promise((res, rej) => {
    let isvalid = false;
    setTimeout(() => {
      if (isvalid) {
        res("success valid");
      } else {
        rej("not valid");
      }
    }, 3000);
  });
}
```

*Promise

then

```
getData()
  .then((data) => {
    console.log(data);
  })
  .catch((err) => {
    console.log(err);
  });
```

Async/ await

```
async function viewDate() {
  try {
    let data = await getData();
    console.log(data);
  } catch (error) {
    console.error(error);
  }
}
```

- *As a quick overview, **async** and **await** keywords allow you to use them and **try/catch** blocks to make functions behave asynchronously.

```
function connect() {  
  return fetch('https://jsonplaceholder.typicode.com/todos/1')  
    .then(response => response.json())  
    .then(json => { return json.title })  
}  
connect().then(x => console.log(x))  
  
async function connectAsync() {  
  return (await fetch('https://jsonplaceholder.typicode.com/todos/1')).json()  
}  
connectAsync().then(x => console.log(x.title))
```

* Async Functions

*It has therefore made sense in recent years to start thinking about providing mechanisms for splitting JavaScript programs up into separate **modules that can be imported when needed**.

***MODULES**

```
///  
//'/js/model/module1.js'  
export class StudentModule {  
    printStudent() {  
        console.log('student from module 1')  
    }  
}
```

*export

```
//'/js/model/module2.js'  
import { StudentModule } from '/js/model/module1.js'  
var x = new StudentModule();  
x.printStudent()
```

*import
